CSE 307: Principles of Programming Languages

Procedures and Parameter Passing

R. Sekar
1. Parameter Passing Mechanisms
Procedure calls:

- Communication between the calling and the called procedures takes place via parameters.

Semantics:

- substitute formal parameters with actual parameters
- rename local variables so that they are unique in the program
  - In an actual implementation, we will simply look up the local variables in a different environment (callee’s environment)
  - Renaming captures this semantics without having to model environments.
- replace procedure call with the body of called procedure
Section 1

Parameter Passing Mechanisms
Parameter-passing semantics

- Call-by-value
- Call-by-reference
- Call-by-value-result
- Call-by-name
- Call-by-need
- Macros
Call-by-value

- Evaluate the actual parameters
- Assign them to corresponding formal parameters
- Execute the body of the procedure.

```c
int p(int x) {
    x = x + 1;
    return x;
}
```

An expression \( y = p(5+3) \) is executed as follows:
- evaluate \( 5+3 = 8 \), call \( p \) with 8, assign 8 to \( x \), increment \( x \), return \( x \) which is assigned to \( y \).
Preprocessing
- create a block whose body is that of the procedure being called
- introduce declarations for each formal parameter, and initialize them with the values of the actual parameters

Inline procedure body
- Substitute the block in the place of procedure invocation statement.
Example:

```c
int z;
void p(int x){
    z = 2*x;
}
main(){
    int y;
    p(y);
}
```

Replacing the invocation `p(y)` as described yields:

```c
int z;
main(){
    int y;
    {
        int x1=y;
        z = 2*x1;
    }
}
```
“Name Capture”

- Same names may denote different entities in the called and calling procedures.
- To avoid name clashes, need to rename local variables of called procedure.
- Otherwise, local variables in called procedure may be confused with local variables of calling procedure or global variables.
Call-by-value (Continued)

- **Example:**
  ```c
  int z;
  void p(int x){
    int y = 2;
    z = y*x;
  }
  main(){
    int y;
    p(y);
  }
  ```

- **After replacement:**
  ```c
  int z;
  main(){
    int y;
    {
      int x1=y;
      int y1=2;
      z = y1*x1;
    }
  }
  ```
Call-by-reference

- Evaluate actual parameters (must have l-values)
- Assign these l-values to formal parameters
- Execute the body.
  ```c
  int z = 8;
  y = p(z);
  ```
- After the call, y and z will both have value 9.
- Call-by-reference supported in C++, but not in C
  - Effect realized by explicitly passing l-values of parameters using “&” operator
Explicit simulation in C provides a clearer understanding of the semantics of call-by-reference:

```c
int p(int *x){
    *x = *x + 1;
    return *x;
}
...
int z;
y = p(&z);
```
Example:

```c
int z;
void p(int x){
    int y = 2;
    z = y*x;
}
main(){
    int y;
    p(y);
}
```

After replacement:

```c
int z;
main(){
    int y;
    {
        int& x1=y;
        int y1=2;
        z = y1*x1;
    }
}
```
Call-by-value-result

- Works like call by value but in addition, formal parameters are assigned to actual parameters at the end of procedure.

```java
void p (int x, int y) {
    x = x +1;
    y = y+ 1;
}
...
int a = 3;
p(a, a) ;
```

- After the call, a will have the value 4, whereas with call-by-reference, a will have the value 5.
Call-by-value-result (Continued)

The following is the equivalent of call-by-value-result call above:

```plaintext
x = a;  y =a 
x = x +1 ;
y =y +1 ;
a =x ;  a =y 
```

thus, at the end, a = 4.
Call-By-Value-Result (Continued)

Example:

```c
void p(int x, y){
    x = x + 1;
    y = y + 1;
}
main(){
    int u = 3;
    p(u,u);
}
```

After replacement:

```c
main(){
    int u = 3;
    {
        int x1 = u;
        int y1 = u;
        x1 = x1 + 1;
        y1 = y1 + 1;
        u = x1; u = y1;
    }
}
```
Call-by-Name

- Instead of assigning l-values or r-values, CBN works by substituting actual parameter expressions in place of formal parameters in the body of callee.

- Preprocessing:
  - Substitute formal parameters in procedure body by actual parameter expressions.
  - Rename as needed to avoid “name capture”

- Inline:
  - Substitute the invocation expression with the modified procedure body.
Example:

```c
void p(int x, y)
{
    int u;
    if (x==0)
        then return 1;
    else{
        return y;
    }
}
main()
{
    int u=5; int v=0;
    p(v,u/v);
}
```

After replacement:

```c
main()
{
    int u;
    {
        if (0==0)
            then return 1;
        else{
            return y;
        }
    }
}
```
Call-By-Need

- Similar to call-by-name, but the actual parameter is evaluated at most once
  - Has same semantics as call-by-name in functional languages
    - This is because the value of expressions does not change with time
  - Has different semantics in imperative languages, as variables involved in the actual parameter expression may have different values each time the expression is evaluated in C-B-Name
Macros

- Macros work like CBN, with one important difference:
  - No renaming of “local” variables

- This means that possible name clashes between actual parameters and variables in the body of the macro will lead to unexpected results.
given

```c
#define sixtimes(y) {int z=0; z = 2*y; y = 3*z;}
main() {
    int x=5, z=3;
    sixtimes(z);
}
```

After macro substitution, we get the program:

```c
main(){
    int x=5,z=3;
    {int z=0; z = 2*z; y = 3*z;}
}
```
Macros (Continued)

- It is different from what we would have got with CBN parameter passing.
- In particular, the name confusion between the local variable z and the actual parameter z would have been avoided, leading to the following result:

```c
main() {
    int x = 5, z = 3;
    {
        int z1=0; // z renamed as z1
        z1 = 2*z; // y replaced by z without
        z = 3*z1; // confusion with original z
    }
}
```
Difficulties in Using Parameter Passing Mechanisms

- CBV: Easiest to understand, no difficulties or unexpected results.
- CBVR:
  - When the same parameter is passed in twice, the end result can differ depending on the order.
  - The order of values assigning back to actual parameters.
  - Otherwise, relatively easy to understand.
Example:

```c
int f(int x, int y) {
    x=4;
    y=5;
}
void g() {
    int z;
    f(z, z);
}
```

If assignment of formal parameter values to actual parameters were performed left to right, then `z` would have a value of 5.

If they were performed right to left, then `z` will be 4.
Difficulties in Using CBR

- Aliasing can create problems.

```c
int rev(int a[], int b[], int size) {
    for (int i = 0; i < size; i++)
        a[i] = b[size-i-1];
}
```

- The above procedure will normally copy b into a, while reversing the order of elements in b.

- However, if a and b are the same, as in an invocation rev(c,c,4), the result is quite different.

- If c is 1,2,3,4 at the point of call, then its value on exit from rev will be 4,3,3,4.
CBN is complicated, and can be confusing in the presence of side-effects.

actual parameter expression with side-effects:

```c
void f(int x) {
    int y = x;
    int z = x;
}
main() {
    int y = 0;
    f(y++);
}
```

Note that after a call to f, y’s value will be 2 rather than 1.
If the same variable is used in multiple parameters.

```c
void swap(int x, int y) {
    int tp = x;
    x = y;
    y = tp;
}

main() {
    int a[] = {1, 1, 0};
    int i = 2;
    swap(i, a[i]);
}
```

When using CBN, by replacing the call to swap by the body of swap: i will be 0, and a will be 2, 1, 0.
Difficulties in Using Macro

- Macros share all of the problems associated with CBN.
- In addition, macro substitution does not perform renaming of local variables, leading to additional problems.
